Please delete the current Abstract in its entirety and  
substitute therefore the enclosed New Abstract.

**NEW ABSTRACT**

A system is provided that includes a rendering apparatus, a server and a network. Content items on the server are identified by respective server content locators, such as a URL. The rendering apparatus has access to local content. Titles of the local content are associated with respective local content identifiers, such as title IDs. The system generates and stores bookmarks, where each bookmark includes a server content locator and a local content identifier. The rendering apparatus render items of the local content and server content items that relate to the local content items. The rendering apparatus renders a server content item indicated by the server content locator of a bookmark conditional on having access to a local content title associated with the local content identifier of the bookmark.
